

## Broad-spectrum synthetic carbohydrate receptors (SCRs) inhibit viral entry across multiple virus families

### Description

Viral pandemics remain a persistent threat to global health and economic stability. Despite advancements in medicine, a lack of broad-spectrum antivirals (BSAs) hinders swift responses to new viral outbreaks. This challenge mainly stems from the absence of universal drug targets across different viral families and the high diversity of viral proteins. The authors tested 57 synthetic carbohydrate receptors (SCRs) for antiviral activity in cell culture, using pseudotyped virus particles (PVPs) from six high-risk viruses spanning three families: Paramyxoviridae, Filoviridae, and Coronaviridae. Four SCRs successfully inhibited all tested PVPs, and their effectiveness was validated against live viruses, including SARS-CoV-2, MERS-CoV, EBOV, MARV, NiV, and HeV.

Notably, SCR005 and SCR007, which showed minimal toxicity, greatly decreased SARS-CoV-2 infection in a severe animal model with just one dose. Mechanistic studies indicate that SCRs attach to viral envelope N-glycans, preventing viral attachment and fusion. These findings highlight conserved viral N-glycans as promising BSA targets and position SCRs as potential prophylactic agents against enveloped viruses with pandemic potential.

**SCRs are inhibitors of SARS-CoV-2, SARS-CoV-1, MERS-CoV, NiV, HeV, EBOV, and MARV entry.** (A) SCRs can inhibit viral entry and membrane fusion. (B) Molecular structures of SCRs with broad-spectrum activity and control compound **SCR013**. (C) VERO-TMPRSS2 cells were pretreated with 10  $\mu$ M of the indicated SCRs, followed by pseudotyped virus infection. Postinfection, intracellular infection levels were evaluated using high-content analysis of luciferase activity, which was then quantified relative to control cells treated with 0.1% dimethyl sulfoxide (DMSO) (based on three independent studies). (D and E) IC<sub>50</sub> and CC<sub>50</sub> values were determined using GraphPad Prism 10 by fitting dose-response curves with a four-parameter logistic (4PL) nonlinear regression model in Vero cells. This was accomplished using the PRNT test and IFA with  $n \geq 3$ . The intermittent line indicates 50% toxicity.
